

# QUEUES

# The Queue ADT

- The **Queue** ADT stores arbitrary objects
- Insertions and deletions follow the first-in first-out scheme
- Insertions are at the rear of the queue and removals are at the front of the queue
- Main queue operations:
  - **enqueue**(object): inserts an element at the end of the queue
  - **dequeue**(): removes the element at the front of the queue
- Auxiliary queue operations:
  - object **front**(): returns the element at the front without removing it
  - integer **size**(): returns the number of elements stored
  - boolean **empty**(): indicates whether no elements are stored
- Exceptions
  - Attempting the execution of dequeue or front on an empty queue throws an **QueueEmpty**

# Example

<i>Operation</i>	<i>Output</i>	<i>Q</i>
enqueue(5)	—	(5)
enqueue(3)	—	(5, 3)
dequeue()	—	(3)
enqueue(7)	—	(3, 7)
dequeue()	—	(7)
front()	7	(7)
dequeue()	—	()
dequeue()	"error"	()
empty()	true	()
enqueue(9)	—	(9)
enqueue(7)	—	(9, 7)
size()	2	(9, 7)
enqueue(3)	—	(9, 7, 3)
enqueue(5)	—	(9, 7, 3, 5)
dequeue()	—	(7, 3, 5)

# Applications of Queues

- Direct applications
  - Waiting lists, bureaucracy
  - Access to shared resources (e.g., printer)
  - Multiprogramming
- Indirect applications
  - Auxiliary data structure for algorithms
  - Component of other data structures

# Array-based Queue

- Use an array of size  $N$  in a circular fashion
- Three variables keep track of the front and rear
  - $f$  index of the front element
  - $r$  index immediately past the rear element
  - $n$  number of items in the queue

# Queue Operations

- Use  $n$  to determine size and emptiness

Algorithm *size()*  
return  $n$

Algorithm *empty()*  
return  $(n = 0)$

# Queue Operations (cont.)

- Operation enqueue throws an exception if the array is full
- This exception is implementation-dependent

```
Algorithm enqueue(o)  
  if size() =  $N - 1$  then  
    throw QueueFull  
  else  
     $Q[r] \leftarrow o$   
     $r \leftarrow (r + 1) \bmod N$   
     $n \leftarrow n + 1$ 
```

# Queue Operations (cont.)

- Operation dequeue throws an exception if the queue is empty
- This exception is specified in the queue ADT

```
Algorithm dequeue()  
  if empty() then  
    throw QueueEmpty  
  else  
     $f \leftarrow (f + 1) \bmod N$   
     $n \leftarrow n - 1$ 
```

# Queue Interface in C++

- C++ interface corresponding to our Queue ADT
- Requires the definition of exception `QueueEmpty`
- No corresponding built-in C++ class

```
template <typename E>
class Queue {
public:
    int size() const;
    bool empty() const;
    const E& front() const
        throw(QueueEmpty);
    void enqueue (const E& e);
    void dequeue()
        throw(QueueEmpty);
};
```

# Application: Round Robin Schedulers

- We can implement a round robin scheduler using a queue Q by repeatedly performing the following steps:
  1. `e = Q.front(); Q.dequeue()`
  2. Service element `e`
  3. `Q.enqueue(e)`
